

RandomForestClassifier

```
class sklearn.ensemble.RandomForestClassifier(n_estimators=100, *,
criterion='gini', max_depth=None, min_samples_split=2, min_samples_leaf=1,
min_weight_fraction_leaf=0.0, max_features='sqrt', max_leaf_nodes=None,
min_impurity_decrease=0.0, bootstrap=True, oob_score=False, n_jobs=None,
random_state=None, verbose=0, warm_start=False, class_weight=None,
ccp_alpha=0.0, max_samples=None, monotonic_cst=None)
```

[\[source\]](#)

A random forest classifier.

A random forest is a meta estimator that fits a number of decision tree classifiers on various sub-samples of the dataset and uses averaging to improve the predictive accuracy and control over-fitting. Trees in the forest use the best split strategy, i.e. equivalent to passing `splitter="best"` to the underlying [DecisionTreeClassifier](#). The sub-sample size is controlled with the `max_samples` parameter if `bootstrap=True` (default), otherwise the whole dataset is used to build each tree.

For a comparison between tree-based ensemble models see the example [Comparing Random Forests and Histogram Gradient Boosting models](#).

Read more in the [User Guide](#).

Parameters:

n_estimators : *int, default=100*

The number of trees in the forest.

❗ **Changed in version 0.22:** The default value of `n_estimators` changed from 10 to 100 in 0.22.

criterion : *{"gini", "entropy", "log_loss"}, default="gini"*

The function to measure the quality of a split. Supported criteria are "gini" for the Gini impurity and "log_loss" and "entropy" both for the Shannon information gain, see [Mathematical formulation](#). Note: This parameter is tree-specific.

max_depth : *int, default=None*

The maximum depth of the tree. If None, then nodes are expanded until all leaves are pure or until all leaves contain less than `min_samples_split` samples.

min_samples_split : *int or float, default=2*

The minimum number of samples required to split an internal node:

- If int, then consider `min_samples_split` as the minimum number.
- If float, then `min_samples_split` is a fraction and `ceil(min_samples_split * n_samples)` are the minimum number of samples for each split.

❗ **Changed in version 0.18:** Added float values for fractions.

`min_samples_leaf` : int or float, default=1

The minimum number of samples required to be at a leaf node. A split point at any depth will only be considered if it leaves at least `min_samples_leaf` training samples in each of the left and right branches. This may have the effect of smoothing the model, especially in regression.

- If int, then consider `min_samples_leaf` as the minimum number.
- If float, then `min_samples_leaf` is a fraction and `ceil(min_samples_leaf * n_samples)` are the minimum number of samples for each node.

❗ **Changed in version 0.18:** Added float values for fractions.

`min_weight_fraction_leaf` : float, default=0.0

The minimum weighted fraction of the sum total of weights (of all the input samples) required to be at a leaf node. Samples have equal weight when `sample_weight` is not provided.

`max_features` : {"sqrt", "log2", None}, int or float, default="sqrt"

The number of features to consider when looking for the best split:

- If int, then consider `max_features` features at each split.
- If float, then `max_features` is a fraction and `max(1, int(max_features * n_features_in_))` features are considered at each split.
- If "sqrt", then `max_features=sqrt(n_features)`.
- If "log2", then `max_features=log2(n_features)`.
- If None, then `max_features=n_features`.

❗ **Changed in version 1.1:** The default of `max_features` changed from "auto" to "sqrt".

Note: the search for a split does not stop until at least one valid partition of the node samples is found, even if it requires to effectively inspect more than `max_features` features.

max_leaf_nodes : int, default=None

Grow trees with `max_leaf_nodes` in best-first fashion. Best nodes are defined as relative reduction in impurity. If None then unlimited number of leaf nodes.

min_impurity_decrease : float, default=0.0

A node will be split if this split induces a decrease of the impurity greater than or equal to this value.

The weighted impurity decrease equation is the following:

$$N_t / N * (impurity - N_{t_R} / N_t * right_impurity - N_{t_L} / N_t * left_impurity)$$

where `N` is the total number of samples, `N_t` is the number of samples at the current node, `N_{t_L}` is the number of samples in the left child, and `N_{t_R}` is the number of samples in the right child.

`N`, `N_t`, `N_{t_R}` and `N_{t_L}` all refer to the weighted sum, if `sample_weight` is passed.

! Added in version 0.19.

bootstrap : bool, default=True

Whether bootstrap samples are used when building trees. If False, the whole dataset is used to build each tree.

oob_score : bool or callable, default=False

Whether to use out-of-bag samples to estimate the generalization score. By default, `accuracy_score` is used. Provide a callable with signature `metric(y_true, y_pred)` to use a custom metric. Only available if `bootstrap=True`.

n_jobs : int, default=None

The number of jobs to run in parallel. `fit`, `predict`, `decision_path` and `apply` are all parallelized over the trees. `None` means 1 unless in a `joblib.parallel_backend` context. `-1` means using all processors. See [Glossary](#) for more details.

random_state : int, RandomState instance or None, default=None

Controls both the randomness of the bootstrapping of the samples used when building trees (if `bootstrap=True`) and the sampling of the features to consider when looking for

the best split at each node (if `max_features < n_features`). See [Glossary](#) for details.

verbose : *int, default=0*

Controls the verbosity when fitting and predicting.

warm_start : *bool, default=False*

When set to `True`, reuse the solution of the previous call to fit and add more estimators to the ensemble, otherwise, just fit a whole new forest. See [Glossary](#) and [Fitting additional trees](#) for details.

class_weight : *{"balanced", "balanced_subsample"}, dict or list of dicts, default=None*

Weights associated with classes in the form `{class_label: weight}`. If not given, all classes are supposed to have weight one. For multi-output problems, a list of dicts can be provided in the same order as the columns of `y`.

Note that for multioutput (including multilabel) weights should be defined for each class of every column in its own dict. For example, for four-class multilabel classification weights should be `[{0: 1, 1: 1}, {0: 1, 1: 5}, {0: 1, 1: 1}, {0: 1, 1: 1}]` instead of `[{1:1}, {2:5}, {3:1}, {4:1}]`.

The "balanced" mode uses the values of `y` to automatically adjust weights inversely proportional to class frequencies in the input data as `n_samples / (n_classes * np.bincount(y))`

The "balanced_subsample" mode is the same as "balanced" except that weights are computed based on the bootstrap sample for every tree grown.

For multi-output, the weights of each column of `y` will be multiplied.

Note that these weights will be multiplied with `sample_weight` (passed through the fit method) if `sample_weight` is specified.

ccp_alpha : *non-negative float, default=0.0*

Complexity parameter used for Minimal Cost-Complexity Pruning. The subtree with the largest cost complexity that is smaller than `ccp_alpha` will be chosen. By default, no pruning is performed. See [Minimal Cost-Complexity Pruning](#) for details. See [Post pruning decision trees with cost complexity pruning](#) for an example of such pruning.

! Added in version 0.22.

max_samples : *int or float, default=None*

If bootstrap is `True`, the number of samples to draw from `X` to train each base estimator.

- If `None` (default), then draw `X.shape[0]` samples.

- If int, then draw `max_samples` samples.
- If float, then draw `max(round(n_samples * max_samples), 1)` samples. Thus, `max_samples` should be in the interval `(0.0, 1.0]`.

! Added in version 0.22.

monotonic_cst : *array-like of int of shape (n_features), default=None*

Indicates the monotonicity constraint to enforce on each feature.

- 1: monotonic increase
- 0: no constraint
- -1: monotonic decrease

If `monotonic_cst` is `None`, no constraints are applied.

Monotonicity constraints are not supported for:

- multiclass classifications (i.e. when `n_classes > 2`),
- multioutput classifications (i.e. when `n_outputs_ > 1`),
- classifications trained on data with missing values.

The constraints hold over the probability of the positive class.

Read more in the [User Guide](#).

! Added in version 1.4.

Attributes:

estimator_ : [`DecisionTreeClassifier`](#)

The child estimator template used to create the collection of fitted sub-estimators.

! Added in version 1.2: `base_estimator_` was renamed to `estimator_`.

estimators_ : *list of `DecisionTreeClassifier`*

The collection of fitted sub-estimators.

classes_ : *ndarray of shape (n_classes,) or a list of such arrays*

The classes labels (single output problem), or a list of arrays of class labels (multi-output problem).

n_classes_ : *int or list*

The number of classes (single output problem), or a list containing the number of classes for each output (multi-output problem).

n_features_in_ : int

Number of features seen during [fit](#).

! Added in version 0.24.

feature_names_in_ : ndarray of shape (n_features_in_,)

Names of features seen during [fit](#). Defined only when `X` has feature names that are all strings.

! Added in version 1.0.

n_outputs_ : int

The number of outputs when [fit](#) is performed.

feature_importances_ : ndarray of shape (n_features,)

The impurity-based feature importances.

oob_score_ : float

Score of the training dataset obtained using an out-of-bag estimate. This attribute exists only when `oob_score` is True.

oob_decision_function_ : ndarray of shape (n_samples, n_classes) or (n_samples, n_classes, n_outputs)

Decision function computed with out-of-bag estimate on the training set. If `n_estimators` is small it might be possible that a data point was never left out during the bootstrap. In this case, `oob_decision_function_` might contain NaN. This attribute exists only when `oob_score` is True.

estimators_samples_ : list of arrays

The subset of drawn samples for each base estimator.

See also

[`sklearn.tree.DecisionTreeClassifier`](#)

A decision tree classifier.

[`sklearn.ensemble.ExtraTreesClassifier`](#)

Ensemble of extremely randomized tree classifiers.

[`sklearn.ensemble.HistGradientBoostingClassifier`](#)

A Histogram-based Gradient Boosting Classification Tree, very fast for big datasets ($n_{\text{samples}} \geq 10,000$).

Notes

The default values for the parameters controlling the size of the trees (e.g. `max_depth`, `min_samples_leaf`, etc.) lead to fully grown and unpruned trees which can potentially be very large on some data sets. To reduce memory consumption, the complexity and size of the trees should be controlled by setting those parameter values.

The features are always randomly permuted at each split. Therefore, the best found split may vary, even with the same training data, `max_features=n_features` and `bootstrap=False`, if the improvement of the criterion is identical for several splits enumerated during the search of the best split. To obtain a deterministic behaviour during fitting, `random_state` has to be fixed.

>>> clf.fit(X, y)
RandomForestClassifier(...)
>>> print(clf.predict([[0, 0, 0, 0]]))
[1]
```

[`apply\(x\)`](#)

[\[source\]](#)

Apply trees in the forest to X, return leaf indices.

Parameters:

X : {array-like, sparse matrix} of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns:

X_leaves : ndarray of shape (n_samples, n_estimators)

For each datapoint x in X and for each tree in the forest, return the index of the leaf x ends up in.

`decision_path(x)`

[\[source\]](#)

Return the decision path in the forest.

! Added in version 0.18.

Parameters:

X : {array-like, sparse matrix} of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns:

indicator : sparse matrix of shape (n_samples, n_nodes)

Return a node indicator matrix where non zero elements indicates that the samples goes through the nodes. The matrix is of CSR format.

n_nodes_ptr : ndarray of shape (n_estimators + 1,)

The columns from `indicator[n_nodes_ptr[i]:n_nodes_ptr[i+1]]` gives the indicator value for the i-th estimator.

property `estimators_samples_`

The subset of drawn samples for each base estimator.

Returns a dynamically generated list of indices identifying the samples used for fitting each member of the ensemble, i.e., the in-bag samples.

Note: the list is re-created at each call to the property in order to reduce the object memory footprint by not storing the sampling data. Thus fetching the property may be slower than expected.

property **feature_importances_**

The impurity-based feature importances.

The higher, the more important the feature. The importance of a feature is computed as the (normalized) total reduction of the criterion brought by that feature. It is also known as the Gini importance.

Warning: impurity-based feature importances can be misleading for high cardinality features (many unique values). See [sklearn.inspection.permutation_importance](#) as an alternative.

Returns:

feature_importances_ : *ndarray of shape (n_features,)*

The values of this array sum to 1, unless all trees are single node trees consisting of only the root node, in which case it will be an array of zeros.

fit(*X, y, sample_weight=None*)

[\[source\]](#)

Build a forest of trees from the training set (X, y).

Parameters:

X : {array-like, sparse matrix} of shape (*n_samples, n_features*)

The training input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csc_matrix`.

y : *array-like of shape (n_samples,) or (n_samples, n_outputs)*

The target values (class labels in classification, real numbers in regression).

sample_weight : *array-like of shape (n_samples,), default=None*

Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

Returns:

self : *object*

Fitted estimator.

`get_metadata_routing()`

[\[source\]](#)

Get metadata routing of this object.

Please check [User Guide](#) on how the routing mechanism works.

Returns:

routing : *MetadataRequest*

A [MetadataRequest](#) encapsulating routing information.

`get_params(deep=True)`

[\[source\]](#)

Get parameters for this estimator.

Parameters:

deep : *bool, default=True*

If True, will return the parameters for this estimator and contained subobjects that are estimators.

Returns:

params : *dict*

Parameter names mapped to their values.

`predict(x)`

[\[source\]](#)

Predict class for X.

The predicted class of an input sample is a vote by the trees in the forest, weighted by their probability estimates. That is, the predicted class is the one with highest mean probability estimate across the trees.

Parameters:

X : *{array-like, sparse matrix} of shape (n_samples, n_features)*

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns:

y : *ndarray of shape (n_samples,) or (n_samples, n_outputs)*

The predicted classes.

`predict_log_proba(x)`

[\[source\]](#)

Predict class log-probabilities for X.

The predicted class log-probabilities of an input sample is computed as the log of the mean predicted class probabilities of the trees in the forest.

Parameters:

X : {array-like, sparse matrix} of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns:

p : ndarray of shape (n_samples, n_classes), or a list of such arrays

The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

`predict_proba(x)`

[\[source\]](#)

Predict class probabilities for X.

The predicted class probabilities of an input sample are computed as the mean predicted class probabilities of the trees in the forest. The class probability of a single tree is the fraction of samples of the same class in a leaf.

Parameters:

X : {array-like, sparse matrix} of shape (n_samples, n_features)

The input samples. Internally, its dtype will be converted to `dtype=np.float32`. If a sparse matrix is provided, it will be converted into a sparse `csr_matrix`.

Returns:

p : ndarray of shape (n_samples, n_classes), or a list of such arrays

The class probabilities of the input samples. The order of the classes corresponds to that in the attribute `classes_`.

`score(X, y, sample_weight=None)`

[\[source\]](#)

Return the mean accuracy on the given test data and labels.

In multi-label classification, this is the subset accuracy which is a harsh metric since you require for each sample that each label set be correctly predicted.

Parameters:

X : *array-like of shape (n_samples, n_features)*

Test samples.

y : *array-like of shape (n_samples,) or (n_samples, n_outputs)*

True labels for `X`.

sample_weight : *array-like of shape (n_samples,)*, *default=None*

Sample weights.

Returns:

score : *float*

Mean accuracy of `self.predict(X)` w.r.t. `y`.

`set_fit_request(*, sample_weight: bool | None | str = '$UNCHANGED$')` →

[RandomForestClassifier](#)

[\[source\]](#)

Request metadata passed to the `fit` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see [sklearn.set_config](#)). Please see [User Guide](#) on how the routing mechanism works.

The options for each parameter are:

- `True`: metadata is requested, and passed to `fit` if provided. The request is ignored if metadata is not provided.
- `False`: metadata is not requested and the meta-estimator will not pass it to `fit`.
- `None`: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- `str`: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

! Added in version 1.3.

Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a [Pipeline](#). Otherwise it has no effect.

Parameters:

sample_weight : *str, True, False, or None*,
default=sklearn.utils.metadata_routing.UNCHANGED

Metadata routing for `sample_weight` parameter in `fit`.

Returns:

self : *object*

The updated object.

set_params(**params)

[\[source\]](#)

Set the parameters of this estimator.

The method works on simple estimators as well as on nested objects (such as [Pipeline](#)). The latter have parameters of the form `<component>__<parameter>` so that it's possible to update each component of a nested object.

Parameters:

****params** : *dict*

Estimator parameters.

Returns:

self : *estimator instance*

Estimator instance.

set_score_request(*, sample_weight: [bool](#) | [None](#) | [str](#) = '\$UNCHANGED\$') →

[RandomForestClassifier](#)

[\[source\]](#)

Request metadata passed to the `score` method.

Note that this method is only relevant if `enable_metadata_routing=True` (see [sklearn.set_config](#)). Please see [User Guide](#) on how the routing mechanism works.

The options for each parameter are:

- `True`: metadata is requested, and passed to `score` if provided. The request is ignored if metadata is not provided.
- `False`: metadata is not requested and the meta-estimator will not pass it to `score`.
- `None`: metadata is not requested, and the meta-estimator will raise an error if the user provides it.
- `str`: metadata should be passed to the meta-estimator with this given alias instead of the original name.

The default (`sklearn.utils.metadata_routing.UNCHANGED`) retains the existing request. This allows you to change the request for some parameters and not others.

! Added in version 1.3.

Note

This method is only relevant if this estimator is used as a sub-estimator of a meta-estimator, e.g. used inside a [Pipeline](#). Otherwise it has no effect.

Parameters:

sample_weight : *str, True, False, or None,*
default=sklearn.utils.metadata_routing.UNCHANGED

Metadata routing for `sample_weight` parameter in `score`.

Returns:

self : *object*

The updated object.
